Non-Contact Measurement Method for 13.56 MHz RFID Tags Using the ENA/ENA-L Network Analyzer

Application Note

Non-Contact Measurement Method for RFIDs

RFIDs, also called IC cards or ID tags, are devices that make it possible to detect the presence of objects and verify their identifications without contacting them. RFIDs have been used since the 1980’s but initially their use was limited to maritime transports, traffic information systems, and some other special applications. Since the middle of 1990’s, RFIDs have been miniaturized at an accelerated rate and they are now widely used. Currently, a number of standards exist that define the frequencies, communication methods, and purposes of RFIDs. This document gives an overview of how to perform non-contact measurements of the resonant frequencies of 13.56 MHz RFID tags. The measurement method introduced in this application note has a proven track record in the fields of development, manufacturing, and maintenance.

Figure 1 shows a simplified setup. A loop antenna used to measure the frequencies is connected to the coaxial end(s) of one or two cables extending from a network analyzer. You can measure the resonant frequency of an RFID tag by holding the RFID tag in front of the measuring antenna.

Figure 1. Measurement setup with reflection or transmission measurement
There are two common practices: one is to perform S11 (reflection) measurements by connecting the antenna via a single coaxial cable to the analyzer and the other is to perform S21 (transmission) measurements by connecting the antenna via two coaxial cables to the analyzer.

Figure 2 is a simplified circuit diagram that represents a measuring antenna and RFID tag connected to a network analyzer. If the RFID tag under test is regarded as a simple LCR parallel resonant circuit, Thomson’s equation gives its resonant frequency as follows:

$$f_0 = \frac{1}{2\pi \sqrt{L_2 C_2}}$$

$$\omega_0 = \frac{1}{\sqrt{L_2 C_2}}$$
Recommended Instruments

ENA/ENA-L network analyzer

The ENA/ENA-L network analyzer (E5061A/E5062A/E5071C) is an optimum choice for measuring RFID resonant frequencies. The ENA/ENA-L network analyzer provides the following features which help perform RFID resonant frequency measurements:

- **Very fast measuring speed**
  The ENA/ENA-L network analyzer boasts an extremely fast measuring speed enabling it to measure the resonant frequencies of multiple RFID tags within one second.

- **Extremely low trace noise**
  Generally, the trace noise characteristics of an analyzer significantly affect the accuracy of resonant frequency measurements. The ENA/ENA-L network analyzer has extremely low trace noise characteristics (as detailed in this application note).

- **Supports both scalar and vector measurements**
  There are two primary methods to measure RFID resonant frequencies: one is based on the scalar quantities (loss) and the other is based on vector quantities (impedance). By using the ENA series, you can perform both the traditional scalar-based analysis and more accurate vector-based analysis.

- **Automatically searches for resonant frequencies**
  The marker search function automatically searches for the resonant frequency of an RFID tag.

- **Supports communications with carrier machines**
  Typical mass production plants use carrier machines to transport tags, which are then held in front of a measuring antenna one after another. Signals for communicating with carrier machines can be output from the handler I/O port on the rear panel of the ENA/ENA-L network analyzer.
  You can use this port to synchronize the analyzer with a carrier machine or supply a carrier machine with PASS/FAIL results based on obtained measurements.

- **Built-in VBA enables full automation**
  The ENA/ENA-L network analyzer comes with a built-in VBA editor. This means that you can automate measurement processes by creating programs within the analyzer, without the need for a PC or external controller.

ECal electronic calibration

Electronic calibration (Ecal) modules consist of connector-specific calibration standards that measure the known devices of the system over the frequency range of interest to detect systematic errors. With simple one-connection operation, they offer excellent accuracy without sacrificing time to calibrate.

ECal electronic calibration kit which provides you with the following benefits:

- Significantly shortens measuring time
- Significantly simplifies measuring procedures
- Significantly reduces connector wear
Differences Between Network and Spectrum Analyzers

Another approach to measuring RFID resonant frequencies is to use the tracking generator function of a spectrum analyzer. This section compares the differences between network analyzer and spectrum analyzer based evaluations.

1. Tracking errors
RFID resonant frequency measurement setups are different: A network analyzer requires calibration while a spectrum analyzer requires normalization. Once the initial measurement setup has been done, the characteristics of amplifiers and other components contained in the analyzer change over time. This produces a measurement error called “tracking error.” A network analyzer performs ratio measurements and therefore it is possible to minimize tracking errors. A spectrum analyzer does not perform ratio measurements which makes it difficult to reduce tracking errors.

2. How measurement repeatability is affected by trace noise
Figure 5 compares RFID resonance characteristics (loss) measured by the ENA-L network analyzer with those measured by the tracking generator function of a spectrum analyzer (both analyzers are configured to complete a measurement cycle at the same elapsed time). As shown in the graph, measurements obtained with the spectrum analyzer have far higher trace noise than those obtained with the network analyzer. The minimum value indicated in the graph is the resonant frequency (delta frequency) of an RFID; when trace noise is too high, a frequency with the minimum value cannot be correctly determined.

3. Measuring speed
The trace noise must be reduced to measure resonant frequencies with better repeatability. Reducing the trace noise requires more averaging steps or a smaller IF bandwidth, either of which results in a longer measuring time. Thanks to its extremely low trace noise characteristics, the ENA/ENA-L network analyzer provides several fold faster measuring speed than a spectrum analyzer.
Customer Use

Sony Corporation’s FeliCa™ Evaluation Lab provides an environment where developers of FeliCa enabled products/solutions can make performance evaluations for various products and how they communicate with other devices. The ENA-L network analyzer (E5061A) is being effectively used in the FeliCa Evaluation Lab. FeliCa is a contactless IC card technology developed by Sony Corporation.

Remove all doubt

Our repair and calibration services will get your equipment back to you, performing like new, when promised. You will get full value out of your Agilent equipment throughout its lifetime. Your equipment will be serviced by Agilent-trained technicians using the latest factory calibration procedures, automated repair diagnostics and genuine parts. You will always have the utmost confidence in your measurements.

Agilent offers a wide range of additional expert test and measurement services for your equipment, including initial start-up assistance, onsite education and training, as well as design, system integration, and project management.

For more information on repair and calibration services, go to:

www.agilent.com/find/removealldoubt

Agilent Open

Agilent Open simplifies the process of connecting and programming test systems to help engineers design, validate and manufacture electronic products. Agilent offers open connectivity for a broad range of system-ready instruments, open industry software, PC-standard I/O and global support, which are combined to more easily integrate test system development.

LXI

LXI is the LAN-based successor to GPIB, providing faster, more efficient connectivity. Agilent is a founding member of the LXI consortium.
